1 INTRODUCTION

1.1 General

The Long Term Monitoring Plan (LTMP) for the Study Area 7 (SA-7) deep overburden and bedrock groundwater remedy was originally developed in 2008 to monitor groundwater conditions relative to the Groundwater Extraction and Treatment (GWET) system. Annual progress reports have been prepared in accordance with this plan since the startup of the GWET system in December 2008 and thus this document represents the sixth such annual performance report. In 2011, the LTMP was expanded to integrate groundwater monitoring requirements for Study Areas 5, 6 and 7 (Project Area). Sampling and analysis within this integrated plan was performed consistent with the requirements set forth in the *Integrated Groundwater Sampling and Analysis Plan for Study Areas 5, 6 and 7* dated March 12, 2014.

1.2 Purpose and Objectives

The purpose of this document is to provide an integrated annual reporting format that characterizes regional groundwater conditions and documents compliance with area-specific remedial objectives. The specific objectives of this approach are to:

- Improve consistency and efficiency in field procedures including sample collection and scheduling.
- Provide a central database for monitoring well specifications and status.
- Provide regional groundwater flow interpretations that consider the impact of features such as subsurface barrier walls, drains, caps, and drawdown from pumping.
- Provide localized groundwater flow maps consistent with the regional contour maps.
- Facilitate preparation of CEA biennial certifications.

1.3 Status of Integrated Monitoring Requirements for 2014

The two primary elements of groundwater monitoring within the Project Area are water level measurements and water quality sampling and analysis. Groundwater level monitoring is conducted quarterly in all available monitoring wells and piezometers. These

data are used to fulfill various reporting requirements as shown on **Table 1-1**. Groundwater quality sampling is conducted in a subset of wells at various times in accordance with the requirements of the various monitoring plans. The status of groundwater sample collection in 2014 is shown on **Table 1-2**.

1.4 Document Organization

In accordance with the approved outline for the Integrated Ground Water Performance Report (IGWPR), this report is organized in terms of its three primary elements; groundwater extraction (Section 3), groundwater elevations and flow direction (Section 4), and groundwater quality (Section 5). These sections are prefaced by a discussion of overall site conditions and events during the reporting period (Section 2). The status of the S-3 Sand Injection/Mass Removal program is summarized in Section 6, and conclusions and recommendations for modifications to the LTMP are provided in Section 7.

2 GENERAL CONDITIONS

Overall conditions within the Project Area were generally uneventful throughout 2014. The GWET system was operational at design rates with the exception of scheduled maintenance and above normal annual precipitation. The S-3 Injection/Mass Removal remedy continued with seven injection events in 2014. Subsurface remedial activities associated with the SA-6 Chromium Remedy continued with the partial construction of the soil containment barrier wall and groundwater dewatering/depressurization pumping for soil excavation.

2.1 Annual Precipitation

Monthly precipitation data recorded at Newark Airport, approximately 2.5 miles southwest of SA-7 are provided in **Table 2-1** and shown on **Figure 2-1**. Precipitation was significantly higher than the 20-year averages in February, May, June, July, October and December. The months of August and September were noticeably drier than their historical averages. Total precipitation in 2014 was 54.69 inches or approximately 8.5 inches above the annual average of 46.25 inches.

2.2 Tidal Monitoring

Tidal fluctuations in the Hackensack River were monitored at the USGS 01392650 Passaic River tide gage in accordance with the New Jersey Tide Telemetry System's standard procedure. A reference point has been established for this gage on the NGVD-1929 vertical datum. This datum is used for all reported groundwater elevation data in this report. The data logger is programmed to record river stage at 6-minute intervals. These data are used to correct groundwater levels for tidal impacts based on tidal lag and efficiency values previously determined for monitoring wells screened in the Intermediate, Deep, and Bedrock zones. There are no tidal influences in the Shallow Zone monitoring wells. The mean tidal elevation is approximately +1.2 feet (NGVD-1929).

2.3 Monitoring Well Inventory

A list of the groundwater monitoring wells currently in service within the Project Area is provided on **Table 2-2**. The wells are organized by hydrogeologic zone. Information regarding the total depth, screen interval, and reference point elevation are also provided. The well locations are shown on the groundwater elevation contour maps provided in **Section 4**. There were no new monitoring wells installed in 2014. Bedrock monitoring wells KP-MW-6BR (Kearny Point) and 090-MW-18BR (up gradient) were deleted from the LTMP in accordance with the recommendations provided in Section 7 of the Integrated Annual Groundwater Performance Report for 2013. Bedrock monitoring well 073-MW-1BR was modified from a Flute well to a shallow bedrock open hole well in June 2014 to

facilitate extending the casing vertically upward to meet proposed grades associated with the SA-6 Chromium Remedy. Numerous monitoring wells were abandoned in accordance with the Monitoring Well Abandonment Plan for SA-6 North and South. Since this is an on-going effort, the status of well abandonment changes frequently. Abandoned wells at the end of 2014 are noted on **Table 2-2**.

3 GROUNDWATER EXTRACTION

The Deep Overburden Groundwater Extraction and Treatment (GWET) system was in operation throughout 2014. Pumping from the contingent pumping system at NJCU was not required and the contingent pumping systems in SA-6 North and South were not installed as of the end of 2014. Groundwater pumping for dewatering of the Deep zone was conducted throughout the year on SA-6 South to facilitate soil excavation.

3.1 GWET System Operation

The GWET system consists of three extraction wells pumping at a combined rate of 54.5 gpm with discharge via independent force mains to the waste water treatment plant located on SA-6 North. Wells PW-1 and PW-2 are located on the Difeo property on the north side of SA-6 North and pump from the Deep and Intermediate zones, respectively. Well 115-MW-203BR was replaced with well 115-MW-215BR in March of 2014. This well is located on the north side of Site 115 and pumps from the upper Bedrock zone.

3.1.1 Pumping Rates

Flow rate monitoring was conducted on each of the three force mains using flow meters located within the treatment plant. The flow rates are controlled by a manually-operated valve and adjusted as necessary to maintain design rates of 40 gpm and 7.5 gpm for wells PW-1 and PW-2 respectively, and 7 gpm for the bedrock extraction well. These rates were maintained throughout the period with the exception of occasional downtime for O&M activities. **Table 3-1** identifies the events that resulted in a shutdown of more than 8 hours. In general, system shutdowns in 2014 were due to routine force main cleaning and activities related to the relocation of the treatment plant.

3.1.2 Force Main Acid Flushing

The GWET force main from extraction well PW-2 to the treatment plant is subject to fouling due to mineralization of groundwater from the Intermediate Zone. As a result, periodic cleaning of the line with hydrochloric acid is conducted on an as-needed basis as determined through monitoring of groundwater discharge trends and line pressures. There were no acid-flushing events conducted during 2014.

3.1.3 Well Redevelopment

Routine groundwater level monitoring in the GWET extraction wells indicated that the pumping level in PW-2 was declining in December 2014. As of this writing, based on the

results of redevelopment efforts in early 2015, the Parties have agreed to install a replacement well (PW-3) in 2015.

3.2 SA-6 North Contingent Groundwater Pumping System

The design of the SA-6 North contingent groundwater pumping system was changed from a series of vertical wells to a trench drain. Installation of the drain was begun in 2014 as part of the SA-6 Chromium Remedy. No pumping from the SA-6 North contingent groundwater pumping system was conducted in 2014.

3.3 SA-6 South Contingent Groundwater Pumping System

The design of the SA-6 South contingent groundwater pumping system was changed from a series of vertical wells to a trench drain. Installation of the drain was begun in 2014 as part of the SA-6 Chromium Remedy and used on an as-needed basis for shallow soil dewatering.

3.4 SA-5 NJCU Contingent Groundwater Pumping System

In accordance with the performance criteria set forth in the *Proposed Triggers for Operation of the SA-5 Contingent Groundwater Extraction and Treatment System* document and the NJCU LTMP, the contingent groundwater pumping system at the NJCU site was not operated during 2014.

3.5 SA-6 South Dewatering Pumping Operations

To facilitate soil excavation activities, groundwater pumping was conducted on SA-6 South to depressurize heads below Stratum D. Groundwater pumping from below Stratum D in 2014 was conducted using depressurization wells DW-1, DW-2, DW-3, DW-4 and DW-5, screened in the Intermediate Zone. In general, active pumping through the year transitioned from east to west to match soil excavation progress. The location of the wells is shown on the Intermediate Zone water level map in Section 4 (**Figure 4-2**) and the general periods of operation for each are summarized in **Table 3-2** below. Actual start/stop dates and daily flow rates were provided in monthly SA-6 Chromium Remedy progress reports.

Table 3-2. Average Flow Rates in SA-6 South Depressurization Wells (gpm)

December					

Note: Blanks indicate no pumping conducted.

4 HYDRAULIC MONITORING

Hydraulic monitoring in 2014 consisted of four quarterly rounds of groundwater elevation measurements in available wells in March, June, September, and December. The measured depth to groundwater was subtracted from the reference point elevation to determine the elevation of the groundwater surface. For those wells that are tidally influenced, the measured values were adjusted using a time-series method developed by the U.S. Geological Survey (Halford, 2006). The results for the four quarterly rounds are provided in **Table 4-1**. Groundwater elevations from the December 2014 round, six years after startup of the GWET system are plotted for the Shallow, Intermediate, Deep, and Bedrock zones on **Figures 4-1** through **4-4**, respectively and on **Figure 4-5** in cross section. Groundwater elevation data are reported in units of feet above mean sea level (amsl) in the NGVD-29 vertical datum.

4.1 Regional Groundwater Flow

4.1.1 Shallow Zone

Groundwater elevations in the Shallow zone range from 13 feet above msl on Site 154 to less than 3 feet above msl near the Hackensack River on Site 163. As a point of reference, the river has a mean tide elevation of approximately +1.2 feet relative to the NGVD-29 datum. As shown on **Figure 4-1**, shallow groundwater flow is generally from east to west across the region, but is locally impacted by subsurface features such as the completed SA-7 and SA-5 barrier walls, the partially completed SA-6 South barrier wall, deep sewer lines that run beneath JCMUA, JCIA, and Route 440, and shallower storm sewers that run along most of the side streets. Groundwater elevations within the shallow soils in the SA-6 North soil containment area varied greatly throughout the year due to recharge from precipitation within the partially installed barrier wall and pumping of the header systems for dewatering.

Shallow groundwater flow is diverted around the SA-7 barrier wall and moves onto SA-6 North and SA-6 South, ultimately discharging to the River or into other subsurface sewers that serve as local groundwater sinks. Areas of locally elevated groundwater are observed in both SA-6 North and SA-6 South along the SA-7 perimeter wall. These elevated zones are likely caused in part by soils with locally reduced hydraulic conductivity, and in part due to their location midway between groundwater discharge areas associated with the River to the west and storm sewers near Route 440 to the east.

At the NJCU site in Study Area 5, groundwater flow is generally from east to west. The north-south oriented “cross-wall” causes groundwater elevations to build up slightly east

of the wall relative to heads on the Home Depot property (Site 117). Further discussion regarding localized groundwater flow on the NJCU site is provided in **Section 4.3**.

4.1.2 Intermediate Zone

Groundwater elevations in the Intermediate zone are shown on **Figure 4-2** and range from over 6 feet above msl in SA-5 to less than mean sea level in the vicinity of the GWET pumping wells. Groundwater is diverted around the SA-7 barrier wall but is not impacted by near-surface features on SA-6 North to the same degree as in the Shallow zone. Groundwater elevations within the SA-7 barrier wall are relatively uniform in the range of two to three feet above msl. The impact of depressurization pumping at SA-6 South is negligible since the DW wells were not in operation during this water level round (December, 2014) as indicated in **Table 3-2**. Vertically, heads within the Intermediate zone are generally one to four feet lower than in the Shallow zone, which indicates a significant downward vertical gradient across Stratum D. This is especially the case west of Route 440 where Stratum D is nearly continuous across the site. **Figure 4-2** also illustrates that the combined groundwater depression in the vicinity of the GWET pumping wells fully encompasses the deep overburden plume and provides an effective capture zone in the upper lacustrine soils.

4.1.3 Deep Zone

Groundwater elevations in the Deep zone (**Figure 4-3**) are similar to those in the overlying Intermediate zone, although the influence of the SA-7 barrier wall is not as prominent. As noted in prior reports, groundwater flow in the Deep zone is, to a degree, able to move beneath the SA-7 barrier wall through gravel lenses in the underlying glacial till/ice contact deposits. At SA-5, the barrier wall does not extend down to the Deep zone and thus does not influence flow. The area of influence of the GWET pumping wells on groundwater flow in the Deep zone is also illustrated on **Figure 4-3**. The resulting combined groundwater depression in the vicinity of the GWET pumping wells fully encompasses the deep overburden plume and provides effective capture in this deeper flow zone.

4.1.4 Bedrock Zone

Groundwater elevation contours in the Upper Bedrock zone are shown on **Figure 4-4** and are relatively uniform compared to those in the overlying lacustrine units. The impact of the GWET pumping well 115-MW-215BR on groundwater flow is evident from the closely-spaced closed contours along the western border of SA-7. This area is characterized by the southwest-northeast trending high-permeability fracture zone which aids in the propagation of the capture zone parallel to the bulkhead as shown on **Figure 4-4**.

4.2 GWET System Capture Zone

Figure 4-5 illustrates that pumping from PW-1 and PW-2 creates a combined zone of influence causing groundwater to flow both laterally and vertically into the capture zone of the wells. The capture zone spans the various semi-confining layers but considering that the vertical anisotropy of the soil is likely on the order of 10:1, the primary component of flow to the wells is horizontal rather than vertical. It should be noted that the cross-section is drawn with a vertical exaggeration of 5X which tends to over-emphasize the vertical component of flow (i.e., the same cross-section drawn at true scale would more effectively illustrate that the majority of flow is horizontal). Based on the data provided in both plan view on **Figures 4-2 and 4-3** and in cross section on **Figure 4-5**, the combined groundwater depression in the vicinity of the GWET pumping wells fully encompasses the deep overburden plume and provides an effective capture zone that meets its design objectives.

4.3 New Jersey City University

Quarterly groundwater elevation data for the NJCU property are compiled in **Table 4-2** and mapped on **Figures 4-6 through 4-9**. NJCU site development activities required that the casing of several monitoring wells be raised and were thus inaccessible during the first quarterly event of the year. Upon completion of the work, the elevation of the new top of casing reference points were determined by survey as shown on **Table 4-2**. The results for each quarter are similar and indicate that groundwater flow is generally to the northwest as it moves onto Sites 90 and 184 from the east but then turns north as it is forced around the various barrier walls that block flow to the south and west. A “dead zone” is thus formed by the confluence of the two walls near the entrance to the Home Depot parking lot and the lack of recharge due to the overlying synthetic liner. As a result, groundwater largely bypasses the Commercial AOC located in this dead zone and thus does not promote the migration of hexavalent chromium to the north onto the Residential Area. This conclusion is supported by groundwater quality data from the sentinel wells as further discussed in **Section 5-5**.

An investigation was conducted in 2014 to re-evaluate groundwater conditions now that the surface has been re-graded and paved. The investigation consisted of monitoring groundwater responses to precipitation events using data loggers in selected wells. The following conclusions were drawn from the results of this evaluation.

- 1) Groundwater head in Sump A was shown to be at or below the elevation of the liner during approximately 90% of the three-month study period.
- 2) Increased head in Sump A due to precipitation events was relatively short-lived, with recovery occurring within approximately 72 hours after the event.

- 3) Potential pressurization of the sand below the liner near Sump A is a relatively infrequent and short-lived phenomenon which, due to slow groundwater flow rates, has no appreciable impact on groundwater flow at the site.
- 4) Based on these results of this study as noted above, it is recommended that ground water level measurements be continued on a quarterly basis, and that measurements do not occur within 72 hours of a measureable rainfall event. This procedure is to provide measurements that are unaffected by a temporary rise in groundwater elevation due to an individual rainfall event.

4.4 SA-7 Perimeter Pools

The LTMP program includes monitoring of the hydraulic gradients across the subsurface containment barrier (SCB) around the perimeter of SA-7. This is accomplished through monitoring of the head in each of the ten “perimeter pools” and comparing these data to groundwater elevations in various shallow piezometers located just outside of the SCB. The location of the perimeter pools, the design pool elevations, and water level trends are provided in **Appendix C**. The hydrographs illustrate the average ground surface elevation, the design pool elevation, the measured pool elevation, and the groundwater elevation in adjacent piezometers outside of the wall. Due to recent construction in SA-6 North and South, many of the former monitoring points have been abandoned in accordance with the approved SA-6 Chromium Remedy. Other piezometers have been installed for soil surcharge monitoring and have been used to supplement the monitoring of head outside of the pools.

Overall, the data indicate that, with a few exceptions, water levels within the SA-7 pools are greater than those outside of the SCB and thus outward gradients are occurring. In prior years, the exceptions included areas outside of pools N-3 and N-4 on Site 087, and a small portion of SA-6 South near pool S-3. However, as shown on the hydrographs in **Appendix C**, heads outside of the wall in these areas have declined significantly due to construction activities which included the redirection of runoff and groundwater dewatering in SA-6 South.

Going forward, groundwater levels outside of the SA-7 SCB wall are expected to continue to decline when the low permeability covers are installed in the open space areas for the SA-6 Chromium Remedy. If this is not the case, the contingent groundwater pumping systems will be available to lower water levels outside of the SA-7 barrier if warranted.

4.5 SA-6 North Containment Cell

A groundwater elevation contour map specific to SA-6 North will be provided in future annual reports after the containment cell has been constructed. Hydraulic gradients across the wall(s) will be determined at the perimeter piezometer locations and compared to performance criteria.

4.6 SA-6 South Containment Cell

A groundwater elevation contour map specific to SA-6 South will be provided in future annual reports after the containment cell has been completed and steady state groundwater levels can be assessed. Hydraulic gradients across the wall(s) will be determined at the perimeter piezometer locations and compared to performance criteria.

4.7 SA-5 Site 117

Groundwater movement beneath Site 117 is generally from northeast to southwest as illustrated on **Figures 4-1 through 4-3**. In the Shallow zone, the sewers beneath Route 440 serve as a groundwater sink and limit the further movement of groundwater to the south and west. In both the Shallow and Intermediate zones, a component of groundwater in the northwestern corner of Site 117 is diverted to the northwest, passing between the SA-7 SCB and the NJCU sheet pile wall. The relatively low groundwater elevations in this area are caused by sewer systems that are actively dewatered by the Jersey City MUA.

4.8 Miscellaneous Events

4.8.1 Depressurization Pumping for Soil Excavation on SA-6 South

To facilitate soil excavation activities, groundwater pumping was conducted on SA-6 South to depressurize heads below Stratum D. Groundwater pumping from below Stratum D in 2014 was conducted using depressurization wells DW-1, DW-2, DW-3, DW-4 and DW-5, screened in the Intermediate Zone. In general, active pumping through the year transitioned from east to west to match soil excavation progress. The location of the wells is shown on the Intermediate Zone water level map (**Figure 4-2**) and the general periods of operation for each are summarized in **Table 3-2**. Actual start/stop dates and daily flow rates were provided in monthly progress reports.

5 GROUNDWATER QUALITY MONITORING

Groundwater quality monitoring within the project area was conducted in 2014 in accordance with the GWET Long-Term Monitoring Plan (LTMP) and the other applicable area-specific monitoring plans as discussed in **Section 1.3** and listed on **Table 1-2**.

5.1 Deep Overburden Regional Plume Monitoring

In 2012 the frequency of regional monitoring of the Deep Overburden Plume changed from annual to biennial (every two years). The last sampling round was in December 2013 and thus the wells were not sampled in 2014. The next round of sampling is scheduled for November 2015.

5.2 GWET Extraction Wells

Groundwater from the three GWET pumping wells was sampled quarterly in 2014 as shown in **Table 5-1**. Samples were analyzed for total and hexavalent chromium and volatile organic chemicals (VOC). The results for hexavalent chromium are plotted on **Figure 5-1** and indicate that concentrations in the Deep zone (PW-1) have declined in an asymptotic fashion to their current level of approximately 35 ppm. Concentrations in the Intermediate zone (PW-2) have declined to about one third of their initial concentration since 2009. The observed slow decline in concentration is likely due to cleaner water being pulled into the pumping wells as confirmed by the in-situ sampling beneath the riverbed sediments discussed in Section 5.9. The cleaner water originates at the margins of the capture zone, including beneath the river, as the plume is pulled back. Hexavalent chromium concentrations in the bedrock have been generally stable at approximately 15 to 20 ppm.

VOC data from the pumping wells are provided in **Table 5-1**. With the exception of carbon tetrachloride and on one occasion chloroform (laboratory estimated value), VOCs have not been detected in the bedrock pumping well. Deep overburden pumping well PW-1 contains the highest VOC concentrations with the most prevalent compounds being chlorinated volatile organics such as trichloroethene (TCE) and its daughter products cis- and trans-dichloroethene and vinyl chloride. These same constituents were detected in the Intermediate zone pumping well PW-2 albeit at lower concentrations. Benzene was also detected in relatively low concentrations in PW-1 and PW-2 samples.

Figure 5-2 illustrates a time-series plot of TCE in each of the GWET pumping wells. The data indicate that concentrations in both PW-1 and PW-2 are in the 50 to 120 ppb range and are continuing to decline slowly. As previously reported, the source of the VOCs in the groundwater is not related to Honeywell.

5.3 SA-6 South

Groundwater monitoring wells were not sampled on SA-6 South in 2014. As shown in **Table 1-2**, the L-well sampling program will be continued after one full year of seasonal hydraulic fluctuations following completion of the Chromium Remedy scheduled for 2017.

5.4 SA-6 North

Groundwater monitoring wells were not sampled on SA-6 North in 2014, with the exception of S-3 Sand Mass Removal Injection program discussed in **Section 6**.

5.5 New Jersey City University

Groundwater samples were collected quarterly in 2014 from the three “sentinel” wells at NJCU. The objective of the monitoring program is to provide early warning of potential chromium migration in groundwater from the Commercial AOC (in the southwest corner of Site 90) to the Residential Area to the north. The results are provided on **Figure 5-3** and indicate that hexavalent chromium was not detected above the reporting limit of 5.5 ppb in any of the samples from well 184-MW-04 and 184-MW-05 during 2014. Hexavalent chromium was reported above the reporting limit (but below 70 ppb) in 184-MW-06 during each round in 2014 at concentrations comparable with previous results. This well is located upgradient of the Commercial AOC and thus these results are not unexpected.

Total chromium was not detected above 70 ppb in wells 184-MW-04 and 184-MW-05 in either the filtered or unfiltered samples throughout 2014. Total chromium was detected at 81.4 ppb in the second quarterly round in the unfiltered sample from 184-MW-06; however, each of the filtered samples collected in 2014 was below the NJGWQC of 70 ppb. These variable results are likely due to differences in turbidity and serves to underscore that trivalent chromium can sorb onto particulates within the sample and be reported in the total chromium result.

5.6 Plume Diversion Area Monitoring

In accordance with the approved L-Well Groundwater Monitoring Plan (L-Well GWMP) which was part of the 100% SA-6 Chromium Remedy Design, the following wells in the Plume Diversion Area of SA-6 South were sampled in May 2013 to provide a pre-remedy baseline and will be sampled once more after the remedy is complete to evaluate if the deep plume in this area has shifted position due to the installation of the soil containment cell.

124-MW-106T	124-MW-103L
124-MW-107T	124-MW-104T
124-MW-G02T	124-MW-104L

119-MW-01T	124-MW-105T
119-MW-02T	124-MW-102T

Locations 124-MW-102T, 124-MW-103L, and 124-MW-107T are located within the open space area and were thus abandoned during excavation activities in 2014. In addition, well 124-MW-104T was damaged during construction and also abandoned in 2014. In accordance with the approved L-Well GWMP and subsequent agreements with Plaintiffs, the post-remedy sampling at these four locations will be conducted using direct push methods after placement of excavated materials and installation of barrier walls but prior to the installation of the cap. This will take place in 2015. The remaining locations will be sampled one year after the SA-6 Chromium Remedy is complete in accordance with the L-Well GWMP. This sampling is expected to take place in 2017.

5.7 SA-5 Site 117

Groundwater sampling for water quality analysis was not conducted at Site 117 in 2014.

5.8 SA-5 Sites 079/153

Groundwater sampling was conducted on July 24, 2014 in existing monitoring wells 079-MW-001 and 079-MW-A02 in accordance with the Remedial Action Report and Confirmatory Sampling Work Plan (September 2011) for Site 079. The results were documented in the Post Treatment Sampling Results Report dated February 2015. Hexavalent chromium was not reported above the reporting limit of 5.5 ppb, and total chromium was reported at a maximum concentration of 5.7 ppb, well below the NJGWQC of 70 ppb. The report recommended that no further groundwater sampling be conducted.

5.9 In-situ Sampling Beneath Riverbed Sediments

In accordance with Section 3.3 of the SA-7 Deep Overburden and Bedrock Groundwater Remedy Long-term Monitoring Plan, in-situ groundwater samples were collected within the lacustrine sand directly beneath the soft riverbed sediments in the Hackensack River. The objective of the sampling was to compare current chromium concentrations in groundwater with those measured in 2004, prior to operation of the GWET pumping system. The sampling was conducted on October 20th and 21st, 2014 at five locations that coincide with prior groundwater samples collected during the “off-site deep overburden investigation” in 2004. The original sample location IDs are shown on **Figure 5-4**, as are the 2004 concentration contours of hexavalent chromium in groundwater taken from Figure

4.4-4 of the Final Groundwater Investigation Report (HydroQual, 2007). Each in-situ groundwater sample was obtained using a GeoProbe sampler from a boat in the same manner as that used in the prior investigation.

Data from the 2014 resampling indicate a significant reduction in the extent of hexavalent chromium with four of the five locations reporting non-detect for hexavalent chromium compared to prior concentrations that ranged from 42 to 218 ppm. The fifth location, PW09-450, remained elevated with a reported hexavalent chromium concentration of 64.2 ppm, which is similar in magnitude to the prior concentration of 43 ppm. The LTMP calls for the next sampling event to take place in 5 years (2019), however, Honeywell may elect to conduct interim monitoring to further evaluate conditions around PW09-450.

6 S-3 INJECTION AND MASS REMOVAL PROGRAM

The S-3 Injection and Mass Removal program was initiated in 2012 and involves the injection of calcium polysulfide (CaSx) into the S-3 Sand beneath the project area in general accordance with the Operations Work Plan for In-Situ Chromium Mass Removal (Cornerstone, February 20, 2012). Changes to the plan, including both the location of the injection wells and the sequence of injection events, have taken place (in consultation with Plaintiffs' representatives) since the plan's inception. In 2013, a subsurface investigation was conducted to identify a suitable location for an injection well east of Route 440 as required by the Mass Removal Consent Decree (May 2010). The investigation found that the S-3 Sand is not present east of Route 440 and thus an injection well was not installed there. Instead, a new injection well (088-IW-03) was constructed west of Route 440 on the former JCIA property and was used for injections in 2014 along with wells 088-IW-01 and 088-IW-02.

6.1 CaSx Injection Events in 2014

Seven CaSx injection events were conducted in 2014 as summarized on **Table 6-1**. Three injection wells (088-IW-01, 088-IW-02, and 088-IW-03) were used as shown on **Figure 6-1**. During each event approximately 3,850 to 4,300 gallons of CaSx was injected into the S-3 Sand formation during the first day. The actual volume varied from event to event and was based on the maximum volume that could be transported in a single tanker truck within DOT weight limitations. As shown on **Table 6-1**, a combination of gravity flow and slight pressurization of the tanker was used to off-load the material at rates ranging from 7 to 14 gpm. The single exception was event # 15 in which the yield of well 088-IW-01 was below its historic performance resulting in a reduced flow rate of 3 to 4 gpm. A bench-scale study was subsequently conducted to evaluate various redevelopment chemicals and the well scheduled for cleaning and re-development in 2015.

During the second and third day of each event, clean water was injected into the well to aid flushing of the CaSx. The total volume of water used was approximately twice the volume of CaSx injected (7,700 to 8,500 gallons). The water was obtained from a MUA fire hydrant and the injection rates generally ranged from 10 to 12 gpm.

6.2 Mass Removal Summary

In accordance with the Operations Work Plan, three replicate samples from each batch were used to determine the sulfide content of the material. The geometric mean of these data was then calculated as shown on **Table 6-2**, and used to estimate the mass of hexavalent chromium stoichiometrically equivalent to the injected volume of CaSx. This calculation was conducted in accordance with the chemical reactions provided in Appendix C of the Operations Work Plan. As shown on **Table 6-3**, the stoichiometric equivalent mass reduced per event in 2014 ranged from 1.22 tons to 1.47 tons with an average of 1.34

tons per event. At the end of 2014, the stoichiometric equivalent of approximately 23 tons of hexavalent chromium had been treated leaving 27 tons remaining in the program. **Figure 6-2** provides a graph of the cumulative mass treated to date

For comparison, the mass of hexavalent chromium removed from the Deep Overburden Plume through historic pumping has also been calculated. As shown on **Figure 6-3**, historic pumping includes operation of the two depressurization wells, 115-DP-1 and 115-DP-2 during the SA-7 soil excavation remedy, and the GWET system pumping that has been ongoing since December 2008. The mass removed was calculated by multiplying the pumping rate of each well by the hexavalent chromium concentration of the discharge. Values for both parameters were determined on a monthly basis from historic records. The results indicate that over 78 tons of hexavalent chromium have been removed through groundwater extraction through the end of 2014.

6.3 Groundwater Quality Monitoring

Groundwater monitoring of injection wells and monitoring wells was conducted in accordance with the Operations Work Plan. Injection wells were sampled several days prior to each injection event, whereas monitoring wells were sampled semi-annually.

6.3.1 Monitoring Well Sampling.

Data from sampling of monitoring wells associated with the S-3 Sand Injection program are provided on **Tables A-1 through A-10 in Appendix A** and further discussed below.

Well 088-MW-G19T: This well is located approximately 400 feet downgradient of injection well 088-IW-01 on the former JCIA property. Parameters used to indicate the presence of the CaSx reductant, such as ORP, calcium, and pH, were relatively consistent throughout the reporting period in this well. Hexavalent chromium concentrations were also relatively unchanged in 2014, ranging from 1,070 to 1,080 ppm.

Well 087-MW-29D: This well is located approximately 750 feet downgradient of injection well 088-IW-03 and is screened in the Intermediate Zone. Parameters used to indicate the presence of the CaSx reductant, such as ORP, calcium, and pH, were consistent throughout the reporting period in this well. Hexavalent chromium concentrations were also generally consistent ranging from 188 ppm to 190 ppm without a trend.

Well 115-DP-1: This is a former depressurization well located approximately 25 feet upgradient from 115-PW-21. (Well 115-PW-21 was used as a temporary injection well on August 20, 2012.) Hexavalent chromium concentrations are shown on **Table A-2** and continued at relatively low levels in the spring 2014 event (14.9 ppm), but then increased to a much higher level at the end of the year (1,300 ppm). As noted in the annual

performance report for 2013, these variable post-injection results are likely due to the fact that 115-DP-1 has a 25-foot long screen that extends approximately 20 feet above the top of the S-3 Sand into the S-2 Sand. Thus, during sampling, the well is likely influenced by both the remnants of the 2012 injection event and the elevated hexavalent chromium concentrations within the overlying S-2 formation. .

GWET Wells: Hexavalent chromium concentrations in extraction wells 087-PW-1 and PW-2 were generally consistent with the long-term downward trend as shown on **Figure 5-1**. Calcium concentrations in 2014 were also consistent with prior data indicating that impacts from the CaSx injections have not reached these wells.

6.3.2 Injection Well Sampling.

Sampling of the injection wells was conducted to assess how long the reductant remains in the groundwater at the point of contact. Injection wells were sampled once prior to the first injection event and then just prior to each injection event as shown on **Tables B-1 through B-10 in Appendix B**. The scope of this portion of the sampling plan has been reduced due to the consistent nature of the results. The fact that hexavalent chromium concentrations have not rebounded between injections is likely due to the establishment of a reductive zone around the well. This zone is capable of treating hexavalent chromium in groundwater that moves into the area from upgradient. Currently, only the well to be used for injection is sampled and only for field parameters. Samples for laboratory analysis are not collected.

Indicator parameters measured in the field include pH, specific conductivity, dissolved oxygen, ORP, and turbidity. These data are shown on **Tables B-6 through B-10**. Of these, ORP appears to be the most reliable indicator of the presence of CaSx (reducing conditions) in groundwater. ORP values initially declined from several hundred mV to less than (minus) -400 mV and have been consistently in the -450 to -500 mV range. Groundwater pH is also a reasonably good indicator since the injected calcium polysulfide has a pH of between 11 and 12. Thus, an increase in pH provides a qualitative indication of calcium polysulfide influence at a specific location. Both ORP and pH indicate that reducing conditions have been established around each of the injection wells and that these conditions will persist for some time, facilitating the reduction of additional hexavalent chromium in groundwater moving into the region from upgradient.

6.4 Planned Activities for 2015

In accordance with the Operations Work Plan, the goal for 2015 will be to inject sufficient reductant in the S-3 Sand to reduce the stoichiometric equivalent of 10 tons of hexavalent chromium. Based on the results from 2014, this will require eight injection events throughout the year.

7 CONCLUSIONS AND RECOMMENDATIONS

7.1 Compliance with Monitoring Requirements

Hydraulic and groundwater quality monitoring conducted in 2014 have fulfilled the various monitoring plan requirements in accordance with **Tables 1-1 and 1-2**.

7.2 Status of Groundwater CEA Certifications

Groundwater Classification Exception Areas were approved by NJDEP on February 16, 2012 for the three principle water bearing zones in the Project Area (Shallow Zone, Deep Overburden, and Bedrock). In 2013, NJDEP notified Honeywell that CEA biennial certifications are not due until the applicable Groundwater Remediation Permits are issued.

7.3 Recommendations for Monitoring Well Network

It is recommended that the abandonment and replacement of selected groundwater monitoring wells be conducted in accordance with the Monitoring Well Abandonment Plan for SA-6 North and South, and the L-Well GWMP.

7.4 Recommendations for Water Level Monitoring Frequency

Groundwater level monitoring will be conducted in accordance with the frequencies specified in the various hydraulic monitoring plans as summarized in **Table 1-1**. There are no recommended changes to these frequencies at this time.

7.5 Recommendations for Groundwater Quality Monitoring Frequency

The frequency of groundwater quality monitoring, well selection, and parameters for analysis are established in the monitoring plans for the various sub-areas. There are no proposed changes to these documents at this time. The next regional sampling event of the deep overburden plume is scheduled for December 2015. Recommendations regarding the frequency of LTMP events beyond 2015 will be considered based on those results.

7.6 Other Recommendations

There are no other recommendations regarding groundwater performance or monitoring in the Project Area at this time.

17	09/21/14	088-IW-02	22.31	4,250	6.04%	1.46	21.60
18	10/29/14	088-IW-03	20.18	3,844	6.31%	1.38	22.97

(a) Mass CaSx Delivered / CaSx density

(b) see Table 6.2

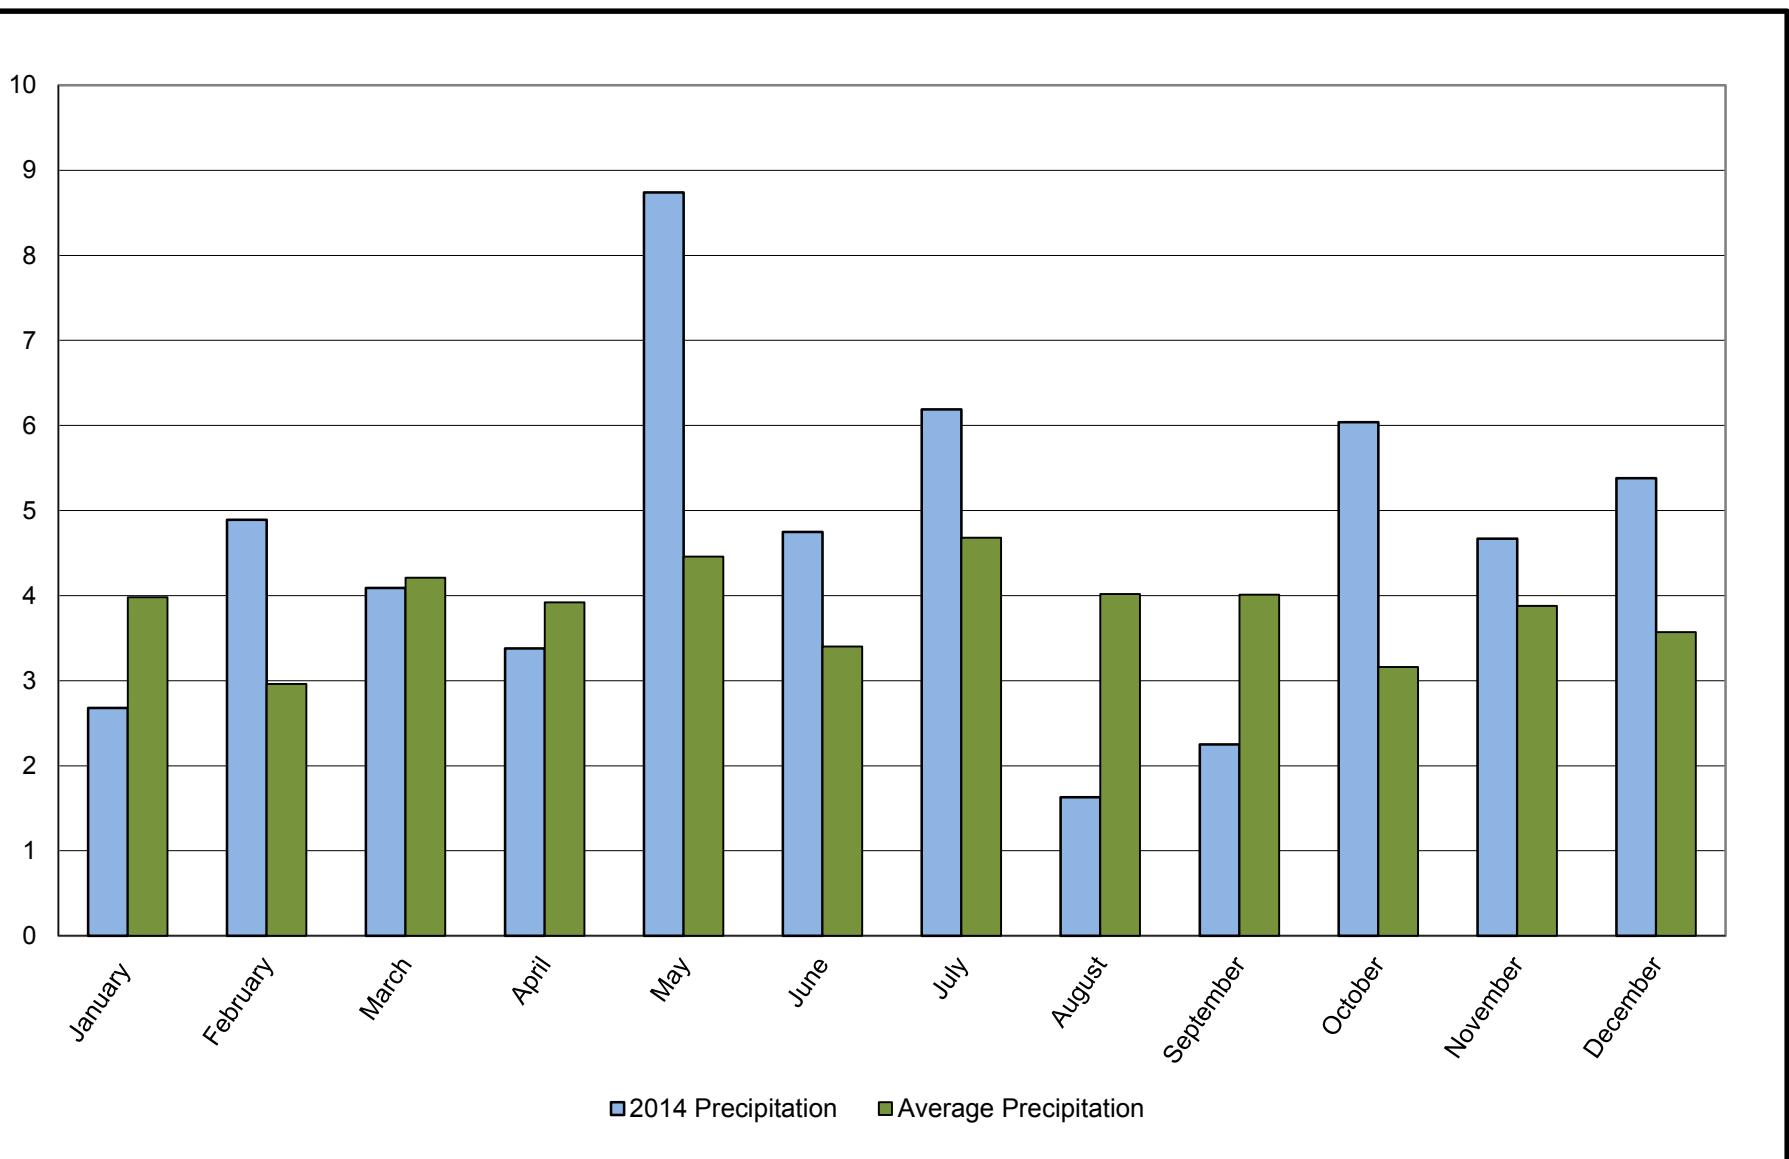

(c) Mass CaSx Delivered × Sulfide% × (51.996/32.065) / 1.5;

The factor 1.5 represents the molar ratio of S(-II) to Cr(VI) in the balanced redox reaction:

51.996 and 32.065 are the atomic masses of Cr and S, respectively

NR: Not Required; the sampling frequency for monitoring wells in the S-3 Mass Removal Program is semi-annual .

NA: Not Analyzed; the collection of filtered samples from the GWET pumping wells is not required.

* Well 087-MW-03 was sampled on a one-time basis at the request of Plaintiffs and is not part of the monitoring plan.

The following wells have been abandoned in accordance with the SA-6 100% Design:

134-W4-DO, 087-MW-001, 087-MW-019, 087-MW-Y20, 115-E1-DO, 115-E1-SO, 125-MW-01, 073-MW-BB-11, 073-MW-Y10, 134-MW-Q08.

The following wells are temporarily inaccessible:

134-MW-V09, E1A-SO, W1-SO, North FS-4
